Chapter 7 describes a modification of Powell's (1964) algorithm for finding a local minimum of a function of several variables without calculating derivatives. The modification is designed to ensure quadratic convergence, and to avoid the difficulties with Powell's criterion for accepting new search directions.

Minimization without Derivatives The derivative-free algorithm is based on Brent in 1971. Normally, a derivative-free algorithm would take more computational resources, however, for a linear search in Quasi-Newton method, one doesn't need a very accurate (machine zero) scheme. Thus, computational resources can be reduced.

Py-BOBYQA is a flexible package for solving bound-constrained general objective minimization, without requiring derivatives of the objective. At its core, it is a Python implementation of the BOBYQA algorithm by Powell, but Py-BOBYQA has extra features improving its performance on some problems (see the papers below for details).
