The use of mD-DSP is fundamental to many application areas such as digital image and video processing, medical imaging, geophysical signal analysis, sonar, radar, lidar, array processing, computer vision, computational photography, and augmented and virtual reality.

Parallel multidimensional digital signal processing - Simply put, parallel processing uses multiple processors working together to solve a single task. Processors can either solve different portions of the same problem simultaneously or work on the same portion of a problem concurrently. This paper discusses digital signal parallel processing as well as the reasons why DSP and parallel

PARALLEL DIGITAL SIGNAL PROCESSING- AN EMERGING MARKET In digital signal processing, parallel processing is a technique duplicating function units to operate different tasks simultaneously. Accordingly, we can perform the same processing for different signals on the corresponding duplicated function units. Further, due to the features of parallel processing, the parallel DSP design often contains multiple outputs, resulting in higher throughput than not parallel.

Parallel multidimensional digital signal processing and - Increasingly, programmable parallel processors are used to address a wide variety of signal processing applications (e.g., scientific, video, wireless, medical, communication, encoding, radar,...

Parallel VSIPLIB: An Open Standard Software Library for - This is done with an analog low pass filter with a cutoff rate set around the Nyquist frequency. This analog filter is known as the anti-aliasing filter. The signal is then used as input into an A/D converter where the signal is converted to a digital signal so that the DSP can handle and process it. The DSP will perform the actions required of it, such as filtering, and then pass the new signal to the D/A.

VLSI Digital Signal Processing Systems: Design and - Abstract - One approach to parallel digital signal processing decomposes a high bandwidth signal into multiple lower bandwidth (rate) signals by an analysis bank. After processing, the subband signals are recombined into a fullband output signal by a synthesis bank. This paper describes an implementation of the analysis and synthesis banks using FPGAs.
